Processing Streams with Apache Flink

Lorenzo Affetti (lorenzo.affetti@gmail.com)

Stream Processing

Processing Data

Essentially it can be broken in 3 simple phases:

- Take input from sources

- Transform it

- Output to sink systems

Let's analyse the first 2 steps to better understand the process: give me examples!

Dataset Types

- Unbounded Datasets:

  - Infinite datasets appended continuously (e.g. machine log data, measurements from a sensor, push notifications);

- Bounded Datasets:

  - Finite and unchanging datasets (e.g. dump of a database, .csv file containing blood measurements for patients)

Expressing the Transformation

- The transformation step can be done in different ways, but, in its essence it carries out some computation.

- The computation can be expressed as a procedure, a computation graph, or an SQL query.

- What really matters is the nature of the source.
How to process data (1/4)

The different ways are (historically):

- **Batch**: processing that runs to completeness in a finite amount of time.

- **Streaming**: possibly infinite processing that executes continuously as long as data is produced.

How to process data (2/4)

- The differences between batch and stream processing are not in their model of computation, but they are <u>intimately connected to the inherent nature of the sources</u>.

- Indeed, **<u>batch processing is a specialised case for stream processing</u>**. I.e. stream processing on finite input.

- Obviously, some sources fit best some processing method and can thus take leverage of their nature, you can figure out which one.
How to process data (3/4)

How to process data (4/4)

The difference in knowing that the input is limited impacts:

- Managing time (out-of-order events)
- Fault-tolerance

Describing Computation: the Graph of Computation (aka topology)

operators / transformations

a source

a sink

Stream Processing —> Flink

Apache Flink

- An **open-source** Stream Processor (SP)

- Leverages every concept we said before: it offers a unified approach to batch and stream processing

- It provides exactly-once processing guarantee in case of failure

- Provides first class state management

- Distributed system management

DataStream & DataSet

Link offers abstractions for unbounded and bounded data

foo foo bar buz

"finite stream"

. bar

. foo

. buz

. foo
Anatomy of a Flink Program

- Obtain an **execution environment**;

- Load/create the **initial data**;

- Specify **transformations** on this data;

- Specify where to put the **results** of your computations;

- **Trigger the program execution**.

Lazy

Lazy Evaluation

- Flink optimizes the graph of computation

- Only when computation is triggered the plan is sent to physical executors

plan

env.execute()

Operators / Transformations

sources

sinks
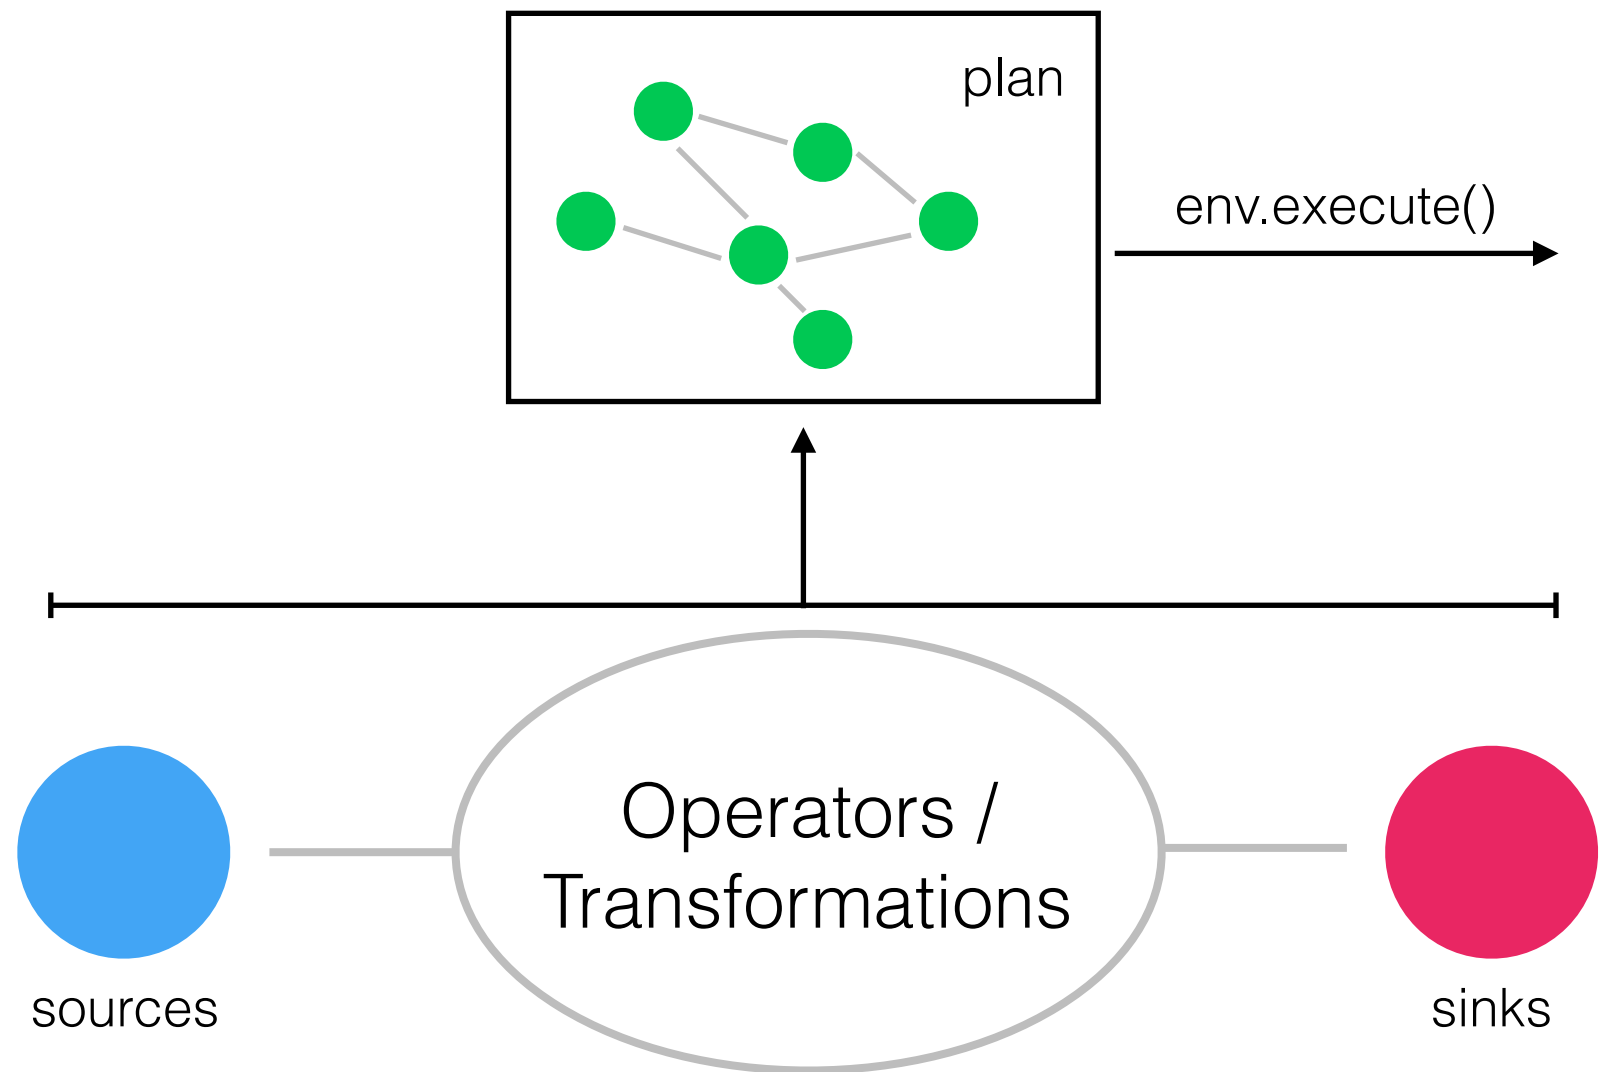

Environment Setup

...

Transformations

Exercise

- Create a stream of a thousand random integers and print it.

Exercise

- Create a stream from a socket source and print it.

Transformations
Map

Transformation	Description

Map
DataStream → DataStream
	Takes one element and produces one element. A map function that doubles the values of the input stream:
	
	``java
	DataStream<Integer> dataStream = //...
	dataStream.map(new MapFunction<Integer, Integer>() {
	    @Override
	    public Integer map(Integer value) throws Exception {
	        return 2 * value;
	    }
	});
	``

Exercise

- Take a stream of a thousand random integers;

- Generate a new stream where the *i-th* element is the square of the *i-th* element in the initial stream;

- Print the resulting stream.

Transformations
Filter

<div style="text-align:center">

| 1 | 4 | 9 | 7 | 2 | 2 |

</div>

$$i \rightarrow i \% 2 == 0$$

| 4 | | | | 2 | 2 |

Filter DataStream → DataStream	Evaluates a boolean function for each element and retains those for which the function returns true. A filter that filters out zero values:
| | ```java
dataStream.filter(new FilterFunction<Integer>() {
    @Override
    public boolean filter(Integer value) throws Exception {
        return value != 0;
    }
});
``` |

Exercise

- Take a stream of a thousand random integers;

- Generate a new stream where the *i-th* element is the <u>string representation</u> of the *i-th* element in the initial stream;

- Generate a new stream containing only the elements that contain the digit "4";

- Print the resulting stream.

Transformations
FlatMap

| 1 | 4 | 9 | 7 | 2 |

i → (i, i)

| 1 | 1 | 4 | 4 | 9 | 9 | 7 | 7 | 2 | 2 |

| **FlatMap** DataStream → DataStream | Takes one element and produces zero, one, or more elements. A flatmap function that splits sentences to words: |

```
dataStream.flatMap(new FlatMapFunction<String, String>() {
    @Override
    public void flatMap(String value, Collector<String> out)
        throws Exception {
        for(String word: value.split(" ")){
            out.collect(word);
        }
    }
});
```

Exercise

- Take a stream of a thousand random integers;

- Generate a new stream of digits (e.g. 1 42 9 —> 1 4 2 9);

- Print the resulting stream.

Stateful Operators

- Some operators need to retain **state**

- Think of examples

Exercise

- Implement a word counter.

- Try to increase the parallelism, what happens (we'll solve it in a minute)?

Dataflow programming and Parallelism
a short* digression

Task and Data Parallelism

- Every operator can run in parallel with the others (*task-parallelism*)

- Every operator can be replicated and process an independent partition of the stream (*data-parallelism*)

Stateful Operators

- We know that some operators need to <u>store an internal state</u> to perform computation (e.g. a rolling count, average, or maximum)

- If the **stateful operator** is replicated, every replica owns its local shard of the state.

- <u>How to manage distributed state</u>?

Transformations
KeyBy

With the keyBy transformation, you can specify how to **extract a key** from every element of the stream.

<u>Two elements with the same key will be in the same partition and processed by the same replica</u>.

KeyBy DataStream → KeyedStream	Logically partitions a stream into disjoint partitions, each partition containing elements of the same key. Internally, this is implemented with hash partitioning. See keys on how to specify keys. This transformation returns a KeyedDataStream.
	`dataStream.keyBy("someKey")` // Key by field "someKey" `dataStream.keyBy(0)` // Key by the first element of a Tuple

Exercise

- Implement a *parallel* word counter.

Keyed State

- The stored state is often a key-value mapping in which the keys are determined by the input KeyedStream.

- Flink provides an abstraction called <u>Keyed State</u> that has nice APIs for accessing the state and automatic state management[1].

[1] State management will be clarified in the part dedicated to fault-tolerance.

Exercise

- Implement a word counter using Flink's Keyed State.

Back to Transformations

Transformations
Reduce

$$(acc, i) \rightarrow acc + i$$

| 1 | 4 | 9 | 7 | 2 | 2 | ⟹ | 25 |

Reduce
KeyedStream → DataStream

A "rolling" reduce on a keyed data stream. Combines the current element with the last reduced value and emits the new value.

A reduce function that creates a stream of partial sums:

```
keyedStream.reduce(new ReduceFunction<Integer>() {
    @Override
    public Integer reduce(Integer value1, Integer value2)
    throws Exception {
        return value1 + value2;
    }
});
```

Exercise

- Take a stream of a thousand random integers;

- Generate a new stream where the *i-th* element is the square of the *i-th* element in the initial stream;

- Generate a stream where the *i-th* element is the sum of every element of the original stream from 0 to position *i*;

- Print the resulting stream.

Transformations
Aggregations

- Flink bakes some standard aggregations on KeyedStreams for you.

- For custom aggregations you should use a stateful map or flatMap[1]

Aggregations KeyedStream → DataStream	Rolling aggregations on a keyed data stream. The difference between min and minBy is that min returns the minimum value, whereas minBy returns the element that has the minimum value in this field (same for max and maxBy).

	``keyedStream.sum(0);
	keyedStream.sum("key");
	keyedStream.min(0);
	keyedStream.min("key");
	keyedStream.max(0);
	keyedStream.max("key");
	keyedStream.minBy(0);
	keyedStream.minBy("key");
	keyedStream.maxBy(0);
	keyedStream.maxBy("key");```

Transformations
Split & Select

Transformations
Split & Select

| **Split**<br>DataStream → SplitStream | Split the stream into two or more streams according to some criterion.<br><br>```java
SplitStream<Integer> split = someDataStream.split(new OutputSelector<Integer>() {
    @Override
    public Iterable<String> select(Integer value) {
        List<String> output = new ArrayList<String>();
        if (value % 2 == 0) {
            output.add("even");
        }
        else {
            output.add("odd");
        }
        return output;
    }
});
``` |
|---|---|
| **Select**<br>SplitStream → DataStream | Select one or more streams from a split stream.<br><br>```java
SplitStream<Integer> split;
DataStream<Integer> even = split.select("even");
DataStream<Integer> odd = split.select("odd");
DataStream<Integer> all = split.select("even","odd");
``` |

Exercise

- Take a stream of a thousand random integers;

- Generate a new stream *A* containing the elements divisible by 5 and the ones by 3;

- Generate a new stream *B* containing the elements divisible by 2;

- Map a square function to *A* and a cube function to *B*;

- Print the resulting streams.

Windowing & Time
a short* digression

Rolling Average

A simple rolling operation outputs a new result as new records are ingested and processed…

t ←······································

(a1, 12), (a2, 15), (a1, 15), (a3, 18), (a3, 18), (a2, 11), (a2, 11), (a1, 12)

14.0,   14.28,   14.16,   14.0,   13.0,   11.33,   11.5,   12.0

Keyed Average

A keyBy operation partitions the stream and let's you compute a partitioned-by-key average.

t ←··

(a1, 12), (a2, 15), (a1, 15), (a3, 18), (a3, 18), (a2, 11), (a2, 11), (a1, 12)

a1   13.0,   13.50,   12.0

··

a2   12.33,   11.0,   11.0

··

a3   18.0,   18.0

Tumbling Window

Take a single partition as example, you can slice time in fixed and non-overlapping slices

t ←·································

```
(a1, 12), (a2, 15), (a1, 15), (a3, 18), (a3, 18), (a2, 11), (a2, 11), (a1, 12)
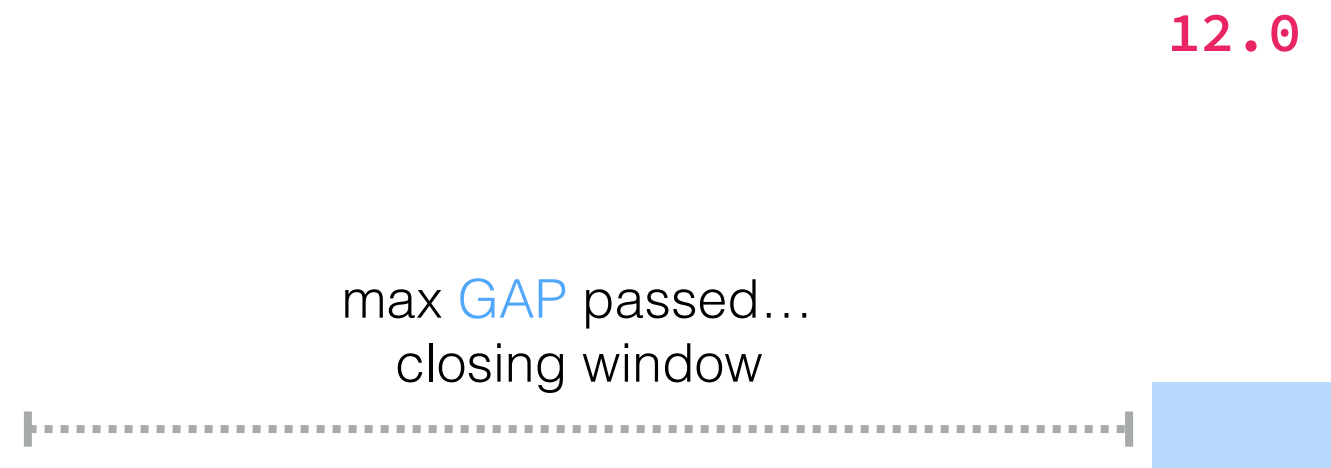

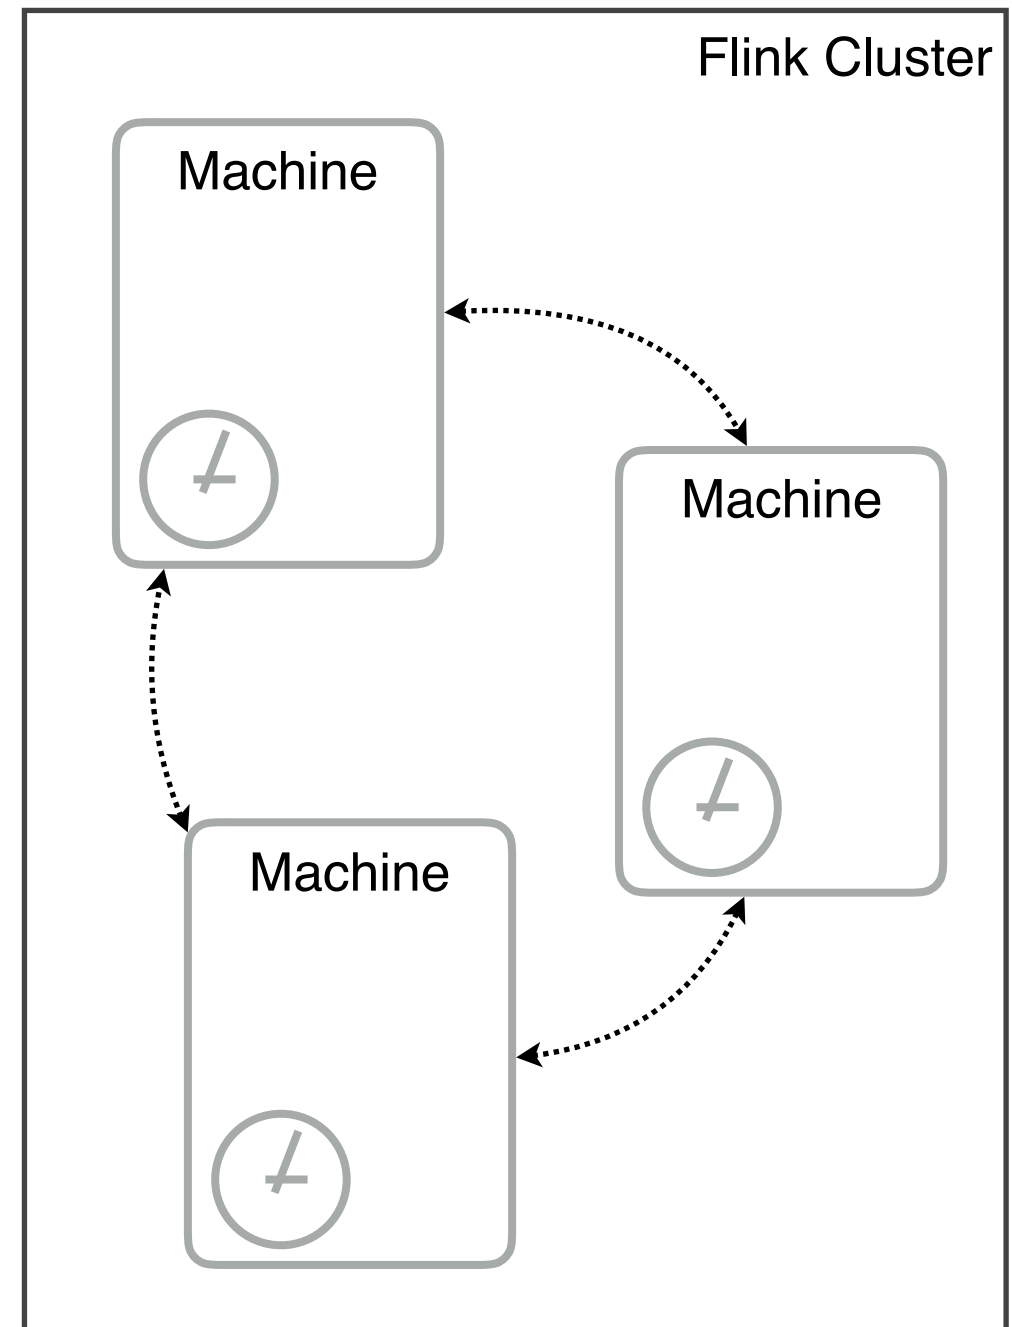

a1   12.0,              15.0,                                          12.0
```

Sliding Window

Take a single partition as example, you can slice time in fixed and ~~non~~ overlapping slices

t ⟵····································

(a1, 12), (a2, 15), (a1, 15), (a3, 18), (a3, 18), (a2, 11), (a2, 11), (a1, 12)

a1   14.0,   15.0,   12.0

Session Window

You can also slice time <u>dynamically</u>, by closing windows if no event happens within a certain GAP.

t ⟵ ·······································

(a1, 12), (a2, 15), (a1, 15), (a3, 18), (a3, 18), (a2, 11), (a2, 11), (a1, 12)

a1   14.0,   12.0

events within GAP

max GAP passed…
closing window

Window

Window KeyedStream → WindowedStream	Windows can be defined on already partitioned KeyedStreams. Windows group the data in each key according to some characteristic (e.g., the data that arrived within the last 5 seconds). See windows for a complete description of windows. `dataStream.keyBy(0).window(TumblingEventTimeWindows.of(Time.seconds(5)));` // Last 5 seconds of data

Two Times
Processing Time

- Processing time is what we experience every day and that <u>we measure with our watches</u>.

- No two events can happen at the very same time.

- In a cluster, every machine has its own clock to measure time.

`(buz), (bar), (buz), (foo), (foo)`

Flink Cluster

Machine

Machine

Machine

The Problem with Processing Time

Processing is affected by:

- Network congestion

- CPU contention & thread scheduling

That's why the **results (that involve time) obtained with processing time are not deterministic and not reproducible**.

Two Times
Event Time

Event time is an abstraction of time as a partial order on a set of provided timestamps.

For one application, the timestamps specify the unique way of measuring time passing[1].

As a result the **results obtained by windowing with event time are deterministic**.

`(2, bar), (4, buz), (6, foo), (6, foo)`

[1] How to make time slide forward in a cluster is treated in appendix.

Extract Timestamp

The user has to specify how the timestamps can be extracted from the ingested data.

Extract Timestamps DataStream → DataStream	Extracts timestamps from records in order to work with windows that use event time semantics. See working with time. `stream.assignTimestamps (new TimeStampExtractor() {...});`

Exercise

- In a building, sensors provides continuous measurements of the temperature in some rooms.

- Calculate the average temperature in every room for the last (event-time) 15 millisecond every (event-time) 5 milliseconds

Back to Transformations

Transformations
(Window) Join

t

| 1 | 4 | 9 | 7 | 2 | 2 |

| 1 | 3 | 9 | 4 | 2 | 1 |

⬇ join

(i1, i2) → i1 + i2

| 1 | 9 | 2 | 2 |

| 1 | 9 | 2 | 2 |

| 2 | 18 | 4 | 4 |

Transformations
(Window) Join

Window Join	Join two data streams on a given key and a common window.

DataStream,DataStream → DataStream	`dataStream.join(otherStream)`
	`    .where(<key selector>).equalTo(<key selector>)`
	`    .window(TumblingEventTimeWindows.of(Time.seconds(3)))`
	`    .apply (new JoinFunction () {...});`

Exercise

- Generate two streams as in slide 30 (use env.fromElements(T…) and the NumberGenerator provided);

- Reproduce the example in slide 30 (you can use Tuples to simplify equality constraints).

Transformations
Union VS Connect

One stream

| 1 | 4 | 9 |

| 1 | 3 | 9 |

union → | 1 | 4 | 1 | 9 | 3 | 9 |

| 1 | 4 | 9 |

| 1 | 3 | 9 |

connect →

| 1 | 4 | 9 |

| 1 | 3 | 9 |

One connected stream.

There is no defined order between the elements.

You can share state upon processing (coMap, coFlatMap)

Transformations
Union VS Connect

Union DataStream* → DataStream	Union of two or more data streams creating a new stream containing all the elements from all the streams. Note: If you union a data stream with itself you will get each element twice in the resulting stream. ```dataStream.union(otherStream1, otherStream2, ...);```

Connect
DataStream,DataStream →
ConnectedStreams
	"Connects" two data streams retaining their types. Connect allowing for shared state between the two streams.
	
	```DataStream<Integer> someStream = //...```
	```DataStream<String> otherStream = //...```
	
	```ConnectedStreams<Integer, String> connectedStreams = someStream.connect(otherStream);```

Exercise

- Take two stream of integers;

- Implement a rolling count both with union and connect.

Exercise

- Take two stream of integers

- *Align* them.

Transformations
Process Function

- They are like low-level FlatMap transformations with access to keyed state and event (or processing) time *timers*.

- The *TimerService* can be used to register callbacks for future time instants.

- When a timer's particular time is reached, the *onTimer(...)* method is called;

- During that call, all states are again scoped to the key with which the timer was created, allowing timers to manipulate keyed state.

Exercise

- Retrieve the temperature data from sensors;

- Output the rooms that did not receive any update for the temperature in the last 5 milliseconds.
